Green payment programs, asymmetric information and the role of fixed costs

Carmen Arguedas∗, Gerdien Meijerink§ and Daan van Soest‡

Abstract

Many conservation programs offer financial compensation to farmers in exchange for socially desired services, such as soil conservation or biodiversity protection. Realization of the conservation objective at minimum cost requires payments to just cover the extra costs incurred by each individual (type of) farmer. In the presence of information asymmetries regarding costs, incentive-compatible contracts can be designed to mitigate excess compensation, but these typically only provide partial improvement because of several distortions. We argue that these distortions are inevitable only if all conservation costs are variable in nature. If there are fixed costs too, we find that the least-cost solution can be incentive compatible. We identify the exact conditions under which these maximum savings can be obtained and conclude that, given the relevance of fixed costs in conservation services provision, incentive-compatible contracts deserve a second look.

Key words: Asymmetric information, environmental benefits, green payments, mechanism design.

JEL Codes: D82, H23, Q57.

1 Introduction

Over the past decade, increasingly more conservation programs have been set up that offer financial compensation to farmers in exchange for the provision of socially desired services, which they would not have
provided otherwise. Such activities include, among others, implementing measures to conserve soils or to protect biodiversity. These so-called green payment programs have been implemented in developed and developing countries alike (see for example OECD 1997 and Ferraro 2001), and usually take the form of contracts between the donor (or regulator) and individual landowners. These contracts specify the type and level of conservation activities the landowner is required to undertake on her land, as well as the amount of money she receives in compensation. Participation is in most instances voluntary, and hence the amount of money offered should at least cover the extra costs incurred.

The problem is that in many instances (i) some landowners can provide conservation services at lower costs than others, and (ii) landowners have better information about these costs than the donor (cf. Ferraro 2005). That means that low-cost landowners have an incentive to overstate the costs of providing specific levels of conservation activity in order to secure more generous compensation payments. Overgenerous payments are typically costly to the donor either because the available funds are limited (in case of a fixed conservation budget) or because there are non-zero costs to raising funds (cf. for example Smith and Tomasi 1999). Hence, the donor has a stake in separating the low– from the high–cost landowners.

In essence, this is a classical mechanism design problem, and over the past years many papers have been published that build on the seminal work of, among others, Mirrlees (1971), Groves (1973), Dasgupta et al. (1979), Harris and Townsend (1981), and Guesnerie and Laffont (1984). Early papers include Smith (1995) who analyzed how mechanism design theory could be applied to the US Conservation Reserve Program, aiming to return a specific amount of agricultural land to na-
ture while minimizing the total amount of compensation payments paid; Smith and Tomasi (1995) who analyzed the problem of limiting pollution runoff from farm land when compensation payments are funded by means of distortionary taxation; and Wu and Babcock (1995 and 1996) who looked at the problem of reducing polluting input use when land quality differs across farmers and where raising funds for compensation is socially costly.

This literature focuses on the case where the donor has full information about all relevant economic characteristics of the various farm types but is unable to identify what type each individual farmer is. Given this form of information asymmetry, the general conclusion is that offering a menu of contracts specifying management prescriptions and associated compensation payments can indeed result in higher social welfare than, for example, a uniform policy applicable to all farmers—but not always (see for example Wu and Babcock 1996: 943).

Despite the fact that these incentive-compatible contracts can be welfare-enhancing, their use is all but widespread (Ferraro 2005). Two reasons may explain this lack of real-world application. First, the information requirements for the donor are substantial, and second the savings in payments (or subsidies) achieved are fairly small. The first reason is obvious, but the second needs somewhat more explanation. The theoretical literature on this topic indeed shows that separating the low—from the high-cost farmers may be possible, but always at a double cost. To ensure incentive-compatibility, contracts are such that compensation payments to the low-cost farmers are still larger than actual costs incurred (in other words, they still receive informational rents), while the

---

1Relevant characteristics include those factors that affect farmers’ opportunity cost of providing conservation services, such as their agricultural production functions, their land quality, etc.
conservation level required from the high-cost farmers is below the complete information solution’s optimal level. Because of this double cost, the net benefits of designing incentive-compatible contracts are likely to be low, and attention seems to have shifted towards alternative instruments, such as for example procurement auctions for conservation contracts (cf. Ferraro 2005: 7; Latacz–Lohmann 2004, Latacz–Lohmann and Schilizzi 2006).

The double cost of incentive-compatible contracts materializes because of one key characteristic of the models developed in this literature, and that is their focus on variable conservation costs. Typically, agents are assumed to differ with respect to a certain characteristic, and this characteristic is assumed to affect the marginal benefits (or costs) of the regulated input. For example, in case of Wu and Babcock (1996), a farmer’s marginal productivity of polluting input use is assumed to be an increasing function of the quality of her land. That means that farmers with high (low) quality land are high-cost (low-cost) producers of conservation services. The presence of these variable costs of conservation services implies that the complete information solution is typically not incentive-compatible. With complete information, the optimal amount of input reduction is a decreasing function of land quality; high-cost conservers should conserve less. This is also the case in the presence of asymmetric information. But whereas in the complete information

\[ \text{2Auctions have their own disadvantages too. To work well, auctions need to be collusion-free as well as simultaneous (rather than sequential, to prevent learning by the farmers about the bids of their peers and the behavior of the regulator); see Latacz-Lohmann and Schillizzi (2006). Preventing collusion is of course difficult in the real world given that, by definition, all potential bidders live in the same region and are able to easily identify their fellow participants in the auction. And auctions are inevitably sequential in nature, as a simultaneous auction of all conservation efforts is infeasible in practice. Therefore, whereas procurement auctions may be a superior instrument than (uniform) contracts, the efficiency gains obtained may be lower than predicted by theory.}\]
solution the associated compensation payments would be increasing in land quality (implying that high-cost farmers receive more money in compensation than low-cost farmers), the second-best contracts under asymmetric information require payments to fall with land quality. Indeed, under asymmetric information the complete information solution is not incentive compatible because it would give low-cost farmers a double incentive to report themselves as high-cost farmers. They would not just be offered less stringent management practices (i.e., less reduction in input use), but larger compensation payments as well (Wu and Babcock 1996: 939).

This paper contributes to this literature by not only taking into account heterogeneity regarding variable conservation costs but also with respect to fixed costs. While these fixed compliance costs can be substantial in practice, they have been largely ignored by researchers and policy makers alike (cf. European Commission 2005: 22). Fixed costs can be the costs of setting up management plans, but they can also take the form of up-front investments without which conservation is not feasible. Using the example of biodiversity oconservation, such investments may include planting trees, digging ponds, or building hedgerows, to create a minimum amount of habitat for species to survive or to establish themselves. But given that the necessary conditions for conservation have been created, the actual amount of biodiversity conservation achieved also depends on decisions like the types of crops cultivated, the amount of fertilizer and pesticides used, etc. Obviously, if farmers continue spraying their fields with highly toxic pesticides, conservation objectives are not achieved even if trees or hedgerows have been planted on the plot’s perimeter. Reducing pesticide use increases species conservation but at increasing costs (in terms of agricultural revenue foregone).
This is just one example where fixed and variable costs matter, but it is not difficult to find other too. And of course it may well be the case that farmers differ in how costly it is to reallocate arable land to conservation structures like ponds, hedgerows and trees, and also differ with respect to their opportunity costs of agricultural output as a function of the reduction in the use of polluting inputs such as fertilizers or pesticides.

We find that when taking into account both fixed and variable conservation costs, incentive-compatible contracts can achieve maximum efficiency after all: that is, the double cost of separation does not necessarily arise. We develop a model with two farmer types differing in both variable and fixed costs, where the objective of the donor is to achieve a certain aggregate conservation objective at minimum cost.\(^3\) We find that separating contracts always result in lower subsidies than uniform contracts, and that maximum efficiency can be achieved especially for intermediately high conservation targets. Our policy conclusion is therefore contrary to the one drawn by Ferraro (2005). Even though the information requirements may be quite substantial, the benefits of implementing separating policies may be sufficiently large to warrant implementation.

The conclusion that fixed costs matter for incentive–compatibility may be surprising. All conservation contracts offered require strictly positive levels of conservation effort, and hence fixed costs are not ex-

---

\(^3\)We therefore implicitly assume the donor to have multiple conservation projects, and then her decision problem is properly characterized as aiming to meet each of her conservation targets at minimum expense. But the reader may think that the case where the donor has a single conservation target and a fixed budget may be relevant too. Then her decision problem is to maximize conservation given the size of her budget. The “maximize conservation” case is the dual of the “minimize cost” case analyzed here, and all our results remain valid in this case. The complete analysis of the “maximize conservation” case is available upon request.
pected to play a role. To provide positive levels of conservation effort, the fixed costs need to be incurred independently of the contract chosen, and hence these fixed costs are sunk from the farmer’s perspective. However, these fixed costs do matter because they affect the amount of compensation payments targeted at each type. The payments consist of two parts; the compensation for the variable costs and for the fixed costs. If a farmer with low variable costs and high fixed costs (relative to the other type) would choose the contract targeted at the other type, she saves on her variable costs (because of the less stringent management requirements imposed). But if she thus declares herself to be of the high–variable–cost type, she would then also receive the compensation payment for that type’s fixed costs. If these are sufficiently smaller than the compensation for the fixed costs of her own type, she prefers to reveal her own type truthfully and choose the contract targeted at her type.

In addition to showing that the complete information solution can be incentive compatible (and under what circumstances), this paper offers two more contributions to the extant literature, one arising because of the existence of fixed costs, and one because of the fixed conservation objective. Regarding the role of fixed costs, we show that in those cases in which the complete information’s optimal solution is not incentive–compatible in the presence of asymmetric information, informational rents accrue to the type with lowest total costs, and hence not necessarily to the type with the lowest variable costs. And if the aggregate conservation objective is fixed, both farmer types’ management requirements are distorted when the complete information solution cannot be implemented: low (high)–variable–cost farmers are required to exert larger (lower) conservation efforts than under the complete infor-
Since the objective of this paper is to analyze the effect of fixed costs on the feasibility of the least-cost solution under asymmetric information, our approach is admittedly simplified in several other respects. First, we abstract from the moral hazard problem that is inherently present in real world situations—that complying with the required conservation levels is hard to detect (but see among others Ozanne et al. 2001 and White 2002). Second, we assume that the donor has perfect information about the (economic) characteristics of the various farmer types but does not know which farmer is of what type. We therefore focus on an asymmetry in status information but not in information collection ability (cf. Goeschl and Lin 2003). Third, we assume that the donor just knows the distribution of types, but does not have any farmer-specific information on the basis of which she could assign prior beliefs regarding the farmer’s type (but see Moxey et al. 1999). Fourth, our model is such that even under asymmetric information, the amount of conservation effort is always higher in case of a conservation scheme than in its absence because we assume that the privately optimal level of conservation effort is zero (but see Motte et al. 2004 and di Corato 2006).

The setup of this paper is as follows. We present the model in section 2, and provide the solution to the complete information problem in section 3. In section 4 we analyze whether the least-cost incentive-compatible contract under asymmetric information is uniform or separating. In section 5, we characterize the optimal policy under asymmetric information and, in particular, we show the circumstances under which the complete information solution is incentive compatible. We draw conclusions in section 6. The details of the optimization problem
under asymmetric information can be found in the appendix.

2 The model

The objective of the donor is to induce a group of farmers to undertake a certain amount of biodiversity conservation effort. There are two types of farmers, indexed $i = 1, 2$, where $n_i > 0$ denotes the total number of farmers of type $i$. Conservation effort of a farmer of type $i$ is denoted by $b_i$. The minimum aggregate level of conservation effort required is $\sum_{i=1}^{2} n_i b_i > 0$. Therefore, $\sum_{i=1}^{2} n_i b_i$.

To provide positive levels of conservation services (i.e., $b_i > 0$), the farmer needs to incur both fixed and variable costs. These two types of costs are denoted by $F_i$ and $c_i(b)$, respectively, and hence total private conservation costs are $C_i(b) = F_i + c_i(b)$. Here, $F_i \geq 0$, and $c_i(b)$ is assumed to be increasing and convex in $b$ with $c_i(0) = c'_i(0) = 0$. Also, we arbitrarily assume that $c''_2(b) > c''_1(b)$ and $c''_2(b) > c''_1(b)$ for all $b > 0$, so that type 1 farmers are always the low–variable–cost providers of conservation services.

Participation is voluntary, which means that farmers of type $i$ need to receive compensation payments (or subsidies, $S_i$) that are at least as large as the amount of conservation costs incurred for the effort prescribed ($S_i \geq C_i(b_i)$). Subsidies are costly in the sense that money spent on the current project cannot be spent elsewhere. Therefore, the objective of the donor is to achieve total conservation effort $\bar{B}$ at minimum budget.

If the donor has perfect information about each particular farmer, the problem is to find the menu $\{(S_1, b_1), (S_2, b_2)\}$ which satisfies the
following:

\[
\begin{align*}
\min \ & \bar{S} = n_1 S_1 + n_2 S_2, \\
\text{s.t.} \ & \bar{B} \leq n_1 b_1 + n_2 b_2, \\
& F_i + c_i (b_i) - S_i \leq 0, \ i = 1, 2.
\end{align*}
\] (1a, 1b, 1c)

However, in case of asymmetric information, the donor has to take into account the incentive compatibility constraints. This means that the menu offered has to be such that each farmer actually prefers the particular policy targeted at its type. That is, the donor needs to ensure that

\[
c_i (b_i) - S_i \leq c_i (b_j) - S_j,
\] (2)

where \(i = 1, 2\) and \(i \neq j\).

The donor can design a uniform policy, that is a single combination of \(b\) and \(S\) that is offered to all farmers. Such a uniform policy, \((S^u, b^u)\), is trivially incentive compatible and that means that one of the participation constraints will not be binding. Since the donor wants to achieve \(\bar{B}\), the uniform policy is straightforward:

\[
b^u = \frac{\bar{B}}{n_1 + n_2}; \quad S^u = \max \{C_1 (b^u), C_2 (b^u)\}.
\] (3)

The donor may also offer a menu of policies consisting of specific combinations of \(S\) and \(b\) targeted at the different farmer types. In case of two farmer types, a separating policy would thus consist of two combinations of subsidies and management requirements, \((S_1^s, b_1^s)\) and \((S_2^s, b_2^s)\).

The key question is whether such a separating scheme is better than a uniform contract, with regard to achieving a given aggregate conservation effort at lower aggregate subsidies.
\section{Complete Information}

Let us first determine the menu of subsidies and management requirements \{(S_1^c, b_1^c), (S_2^c, b_2^c)\} which yields the complete information solution to problem (1). The Lagrangian is the following:

\[ L = n_1 S_1 + n_2 S_2 + \mu [\bar{B} - n_1 b_1 - n_2 b_2] + \sum_{i=1}^2 \lambda_i [F_i + c_i (b_i) - S_i], \]

where \( \mu \geq 0, \lambda_i \geq 0 \) are the Kuhn–Tucker multipliers associated with the conservation objective and the participation constraints, respectively. The first–order conditions are:\footnote{Our assumptions ensure that these are necessary and sufficient conditions for an optimum.}

\begin{align*}
\lambda_i c_i' (b_i) + \mu n_i &= 0; \\
n_i - \lambda_i &= 0; \\
\mu [\bar{B} - n_1 b_1 - n_2 b_2] &= 0; \\
\lambda_i [F_i + c_i (b_i) - S_i] &= 0; \quad F_i + c_i (b_i) - S_i \leq 0. 
\end{align*}

where \( i = 1, 2 \). From (4b), we obtain \( \lambda_i = n_i > 0 \). This implies \( F_i + c_i (b_i^c) - S_i^c = 0 \) (see (4d)) and \( \mu = c'_1 (b_1^c) = c'_2 (b_2^c) \) (see (4a)). In words, the required conservation efforts are such that marginal costs are equal, and subsidies are paid to exactly cover conservation costs. Since \( c'_2 (b) > c'_1 (b) \) for all \( b > 0 \), we trivially have \( b_1^c > b_2^c \). Thus, the effort level required from type 1 farmers is larger than that of type 2 farmers. However, there is no trivial ranking with respect to the required subsidy levels because of the presence of fixed costs. Clearly, \( c_1 (b_1^c) > c_2 (b_2^c) \), but \( S_1^c > (\leq) S_2^c \) if and only if \( F_2 - F_1 < (>) c_1 (b_1^c) - c_2 (b_2^c) \).

\footnote{This can be seen as follows. The first order condition is that \( \mu = c'_1 (b_1^c) = c'_2 (b_2^c) \), and hence \( \frac{db_1^c}{db_2^c} = \frac{c'_1}{c'_2} > 1 \). Now for any level of \( b_2^c \) (with corresponding \( b_1^c \)), we have \( \frac{d(c_1 (b_1^c) - c_2 (b_2^c))}{db_2^c} = c'_1 (b_1^c) \frac{db_1^c}{db_2^c} - c'_2 (b_2^c) = \mu \frac{db_1^c}{db_2^c} > 0 \). Straightforward integration yields \( c_1 (b_1^c) - c_2 (b_2^c) > 0 \) for all \( b_2^c > 0 \).}
4 Asymmetric Information: Uniform versus Separating Policies

Let us now turn to the case where information is asymmetric. Each individual farmer knows her type; the donor only knows the characteristics of the two types \((F_i \text{ and } c_i(b), \ i = 1, 2)\) and the total number of farmers \((n_1 \text{ and } n_2)\) but does not know which farmer is of what type. Before characterizing the exact optimal policy (in the next section), we first establish whether the optimal solution under asymmetric information is separating, or uniform. Here, the donor needs to take into account the incentive compatibility constraints given in \((2)\), and the problem is to find the menu \(\{(S_1, b_1), (S_2, b_2)\}\) which satisfies the following:

\[
\min \hat{S} = n_1 S_1 + n_2 S_2, \quad (5a)
\]

\[
\text{s.t. } B \leq n_1 b_1 + n_2 b_2, \quad (5b)
\]

\[
F_i + c_i(b_i) - S_i \leq 0, \quad i = 1, 2, \quad (5c)
\]

\[
c_i(b_i) - S_i \leq c_i(b_j) - S_j, \quad i, j = 1, 2, \ i \neq j. \quad (5d)
\]

Isocost functions are a useful tool to evaluate farmer preferences when comparing multiple policy combinations. These functions represent the sets of policy combinations \((S,b)\) for which farmer type \(i\)’s total (net) costs are constant and equal to \(k_i\): \(k_i = F_i + c_i(b) - S\). Since \(\frac{\partial b}{\partial S}|_{k_i} = \frac{1}{c_i'(b)}\), isocost functions are upward-sloping and concave in \((S,b)\) space; see Figure 1. Because \(c_2'(b) > c_1'(b)\), the isocost function of a type 1 farmer is strictly steeper in any policy combination \((S,b)\) than that of a type 2 farmer; \(\frac{\partial b}{\partial S}|_{k_1} > \frac{\partial b}{\partial S}|_{k_2}\). Finally, costs decrease whenever the required effort level is lower and the subsidy is larger, and hence isocost functions located to the south-east are preferred to those located to the north-west (as is illustrated in Figure 1 for type 1 farmers, where \(\bar{k}_1' > \bar{k}_1\)). Or, put differently, for a given isocost function, all policy combinations
Figure 1: A subsidy-saving deviation from the least-cost uniform policy.

located to the south–east (north–west) of this function result in lower (higher) net total costs.

Figure 1 allows us to show the intuition behind the result that under asymmetric information the least–cost uniform policy (3) is never optimal. Consider \((S^u, b^u)\) as depicted in Figure 1. We can have either \(\bar{k}_1 = 0\) (if \(C_1(b^u) > C_2(b^u)\), implying \(\bar{k}_2 < 0\)) or \(\bar{k}_2 = 0\) (if \(C_1(b^u) < C_2(b^u)\), implying \(\bar{k}_1 < 0\)). We now prove that the total amount of subsidies can always be decreased (as compared to the uniform case) by designing a menu of policy combinations. We do this by showing that the aggregate amount of subsidies offered falls if the donor sets the policy combina-
tion targeted at type 1 farmers on the $k_1 = \bar{k}_1$ line to the north–east of $(S^v, b^v)$, and the combination targeted at type 2 farmers on the $k_2 = \bar{k}_2$ line to the south–west of $(S^u, b^u)$. Such a set of combinations is both incentive–compatible and decreases the total amount of subsidies paid.

The analysis is as follows. First note that decreasing $b_2$ implies increasing $b_1$ as the aggregate conservation objective $\bar{B}$ always needs to be met. Totally differentiating the conservation constraint yields $\frac{db_1}{db_2} = -\left(\frac{n_2}{n_1}\right)$. Next, given $db_i$ we can infer the required increase in subsidies ($dS_i$) such that the farmer’s total net costs remain unchanged; this equals $\frac{\partial S_i(b^u)}{\partial b} = \frac{c_i'(b^u)}{b}$. Now the aggregate amount of subsidies required ($\tilde{S}$) varies with $b_2$ as follows: $d\tilde{S}/db_2 = n_1 \frac{\partial S_1(b^u)}{\partial b_1} \frac{db_1}{db_2} + n_2 \frac{\partial S_2(b^u)}{\partial b_2} = n_2 (c_2'(b^u) - c_1'(b^u)) > 0$. Therefore, starting from $(S^u, b^u)$, marginally decreasing $b_2$ (and concomitantly increasing $b_1$) reduces the total amount of subsidies paid. Finally, when moving along the two $k_i = \bar{k}_1$ lines as indicated, each farmer strictly prefers the new policy combination targeted at her type.

Hence, the uniform policy is never optimal; independent of the number of farmers being of type 1 or type 2 ($n_1$ and $n_2$), it is always cheaper to induce the low–cost (high–cost) farmers to undertake slightly more (less) conservation effort. Also note that incentive compatible policies are then characterized by higher (lower) effort levels and subsidies intended for the low (high) variable cost type. Note that this result is independent of the level of the fixed costs.

5 The Optimal Policy under Asymmetric Information

Let us now address the question whether the complete information solution (4a)–(4d) can be incentive compatible in the presence of fixed costs. The complete information solution is incentive compatible if and
only if (5c) holds with strict equality for \( i = 1, 2 \), and (5d) is met for \((i, j) = (1, 2)\) and \((i, j) = (2, 1)\). Combining these four equations, we find that the complete information solution is incentive-compatible if and only if

\[
c_2(b_2^c) - c_1(b_2^c) \leq F_1 - F_2 \leq c_2(b_1^c) - c_1(b_1^c).
\] (6)

A necessary condition for (6) to hold is that \( F_1 > F_2 \geq 0 \). The reason is that \( c_2'(b) > c_1'(b) \) for all \( b > 0 \), and hence \( c_2(b) - c_1(b) > 0 \). That means that when \( F_2 \geq F_1 \geq 0 \), the first inequality in condition (6) never holds. In case \( F_1 > F_2 \geq 0 \), the condition is met for at least some values of \( F_1 \) and \( F_2 \): because \( b_1^c > b_2^c \) and \( c_2'(b) > c_1'(b) \) for all \( b > 0 \), we have \( c_2(b_2^c) - c_1(b_2^c) < c_2(b_1^c) - c_1(b_1^c) \).\(^6\)

The reason why the two fixed costs appear in the incentive compatibility constraint is that their levels affect the amount of subsidies provided. This result is clear when analyzing the two inequalities in (6) separately. The first inequality can be rewritten as \( c_2(b_2^c) + F_2 \leq F_1 + c_1(b_2^c) \), and hence \( 0 \leq F_1 + c_1(b_2^c) - S_2^c \). In words, this inequality is about the incentives for type 1 farmers to misrepresent their type under the complete information solution. Their net costs are zero if they choose the policy combination aimed at their type, and this is incentive compatible if their net costs are positive if they misrepresent themselves. So, even though \( c_1(b_2^c) < c_1(b_1^c) \), type 1 farmers may still prefer the policy targeted at their type if \( S_2^c \) is sufficiently small compared to \( S_1^c \), and this is the case if \( F_2 \) is sufficiently small compared to \( F_1 \). And a similar analysis applies to the second inequality, which can be rewritten as \( c_1(b_1^c) + F_1 \leq c_2(b_1^c) + F_2 \) so that \( 0 \leq F_2 + c_2(b_1^c) - S_1^c \). Type 2 farmers have an incentive to choose

\(^6\)Note that together with \( c_1'(b) > c_2'(b) \) for all \( b > 0 \), the cases \( F_2 \geq F_1 \) and \( F_1 > F_2 \) exhaust all possible combinations of levels of fixed costs being high or low, and the levels of variable costs being high or low.
the combination aimed at their type because \( c_2 (b_2^s) < c_2 (b_1^c) \), but they will only do so if \( S_1^c \) (\( S_2^c \)) is sufficiently low (high), which is the case if \( F_1 \) (\( F_2 \)) is sufficiently small (large).\(^7\)

This can also be shown graphically. Let us first consider the case where \( F_2 \geq F_1 \geq 0 \), so that \( C_2(b) > C_1(b) \) for all \( b > 0 \), as represented in Figure 2. Here, the \( k_1 = 0 \) line is strictly located to the north–west of the \( k_2 = 0 \) line. Therefore, type 1 farmers prefer the contract intended for type 2 farmers. For \( b = 0 \), the minimum amount of subsidies required when farmers are forced to invest is \( S_i = F_i \), and \( F_2 \geq F_1 \) implies that the horizontal intercept of the \( k_1 = 0 \) is (weakly) to the left of that of the \( k_2 = 0 \) line. Next, because \( \frac{db}{dS}\big|_{k_1} > \frac{db}{dS}\big|_{k_2} \) for all \( b > 0 \), the \( k_1 = 0 \) line is located strictly to the north of the \( k_2 = 0 \) line. Therefore, in this case the complete information solution (4a)–(4d) is never incentive compatible.

The optimal policy when \( F_2 \geq F_1 \geq 0 \) is characterized by the following conditions (for a formal proof see the Appendix):

\[
\begin{align*}
n_1 \left[ c'_2 (b_2^s) - c'_1 (b_1^c) \right] &= n_2 \left[ c'_1 (b_1^c) - c'_2 (b_2^s) \right], \quad (7a) \\
\overline{B} &= n_1 b_1^s + n_2 b_2^s, \quad (7b) \\
S_2^s &= F_2 + c_2 (b_2^s), \quad (7c) \\
c_1 (b_1^c) - S_1^s - c_1 (b_2^s) + S_2^s &= 0. \quad (7d)
\end{align*}
\]

In this case, type 1 farmers have an incentive to misrepresent their type under the complete information solution, but type 2 farmers do not. Therefore, the farmers of the latter type receive a subsidy that just covers their conservation costs (7c), whereas the former type receives an informational rent so that their incentive compatibility constraint is

\(^7\)Note that this case includes \( F_1 = F_2 = 0 \); the first best is never incentive compatible if there are only variable conservation costs.
Figure 2: Incentive compatibility of the complete information contracts if $F_2 \geq F_1 \geq 0$. 
binding (7d). Therefore, the optimal policy is that the subsidy intended for type 1 farmers \( (S^*_1) \) more than covers their private costs of exerting the effort level \( b^*_1 \), and the informational rent equals \( R_1 \equiv S_1 - F_1 - c_1(b_1) \geq 0 \). The question is then what levels of conservation effort should be imposed on the two farmer types. Substituting (7c) into (7d), adding and subtracting \( F_1 \) and rewriting yields

\[ R_1 = c'_2(b_2) - c'_1(b_2) + F_2 - F_1 > 0. \]

Changing \( b_1 \) affects \( R_1 \) and, using \( db_2/db_1 = - (n_1/n_2) \) (because of (7b)), we have

\[ \frac{dR_1}{db_1} = [c'_2(b_2) - c'_1(b_2)](db_2/db_1) = - (n_1/n_2)[c'_2(b_2) - c'_1(b_2)] < 0. \]

Increasing the amount of conservation effort required from type 1 farmers increases their conservation costs and thus lowers the informational rent they receive. Therefore, the ‘golden rule’ of \( c'_1(b_1) = c'_2(b_2) \) (see the solution of (4)) needs to be modified by adding \( dR/db_1 \) to the LHS, which yields:

\[ c'_1(b^*_1) - \frac{n_1}{n_2} [c'_2(b^*_2) - c'_1(b^*_2)] = c'_2(b^*_2), \]

and this is identical to (7a). Thus, the net marginal cost of type 1 farmers are larger than those of type 2 farmers: \( c'_1(b^*_1) > c'_2(b^*_2) \). Therefore, \( b^*_1 > b^*_1 \) and \( b^*_2 < b^*_2 \) and, consequently, \( S^*_1 > S^*_1 \) and \( S^*_2 < S^*_2 \). Since there is a fixed aggregate conservation objective, \( B \), both individual effort levels are adjusted to satisfy the optimality condition and the constraint \( B \).

Now, let us consider the case where \( F_1 > F_2 \geq 0 \), so that the total costs incurred by type 2 farmers are not always larger than those incurred by type 1 farmers. This case implies that \( k_2 = 0 \) and \( k_1 = 0 \) intersect at one particular level of \( b \), labelled \( \tilde{b} \) in Figure 3. We know from the previous section that the optimal solution is always a separating policy, and we show that in this case the complete information’s optimal (separating) policy may even be incentive compatible. Here, the outcome depends on the relative values of the fixed costs incurred, the
aggregate conservation objective and on the variable cost functions.

Suppose that the complete information solution is such that either $b_2^* < b_1^* < \tilde{b}$, or $\tilde{b} < b_2^* < b_1^*$. That means that in either case, one of the two policy combination is located on the dotted part of either of the two isocost functions in Figure 3, and the complete information’s optimal policy is not incentive compatible. If $\tilde{b} < b_2^* < b_1^*$, the situation is analogous to the one depicted in Figure 2 and hence here type 1 farmers strictly prefer the contract intended for type 2 farmers. In fact, condition $\tilde{b} < b_2^* < b_1^*$ is equivalent to $F_1 - F_2 < c_2(b_2^*) - c_1(b_2^*)$, which violates (6). In that case, the optimal separating policy is again (11),
that is an informational rent must be given to type 1 farmers.

If, however, $b_2^c < b_1^c < \hat{b}$, type 2 farmers strictly prefer the contract intended for type 1 farmers. Here, condition $b_2^c < b_1^c < \hat{b}$ is equivalent to $F_1 - F_2 > c_3 (b_1^c) - c_1 (b_1^c)$. The optimal policy is then again a separating contract, characterized now by the following conditions:

$$n_2 \left[ c_2' (b_1^c) - c_1' (b_1^c) \right] = n_1 \left[ c_1' (b_1^c) - c_2' (b_2^c) \right], \quad (9a)$$

$$\overline{B} = n_1 b_1^s + n_2 b_2^s, \quad (9b)$$

$$S_1^s = F_1 + c_1 (b_1^c), \quad (9c)$$

$$c_2 (b_2^s) - S_2^s - c_2 (b_1^s) + S_1^s = 0. \quad (9d)$$

The interpretation is analogous to that of (11). Type 1 farmers have no incentive to misrepresent their type when facing the complete information’s optimal policy menu, but type 2 farmers do. Therefore, type 1 farmers are just compensated for their extra costs (9c), but type 2 farmers receive an informational rent such that their incentive compatibility constraint (9d) is binding. From (9b)–(9d) we can derive (9a) in exactly the same fashion as we obtained (7a) from (7b)–(7d). In this case, we also have $b_1^s > b_1^c$, $b_2^c < b_2^c$, $S_1^s > S_1^c$ and $S_2^s < S_2^c$.

If, however, $b_2^c \leq \hat{b} \leq b_1^c$ (with at least one of the two inequalities being strict), the complete information solution is incentive-compatible, since condition (6) holds. For type 2 farmers the difference in subsidies $(S_1^c - S_2^c)$ is always smaller than the increase in variable costs they incur when representing themselves as type 1 farmers; for type 1 farmers the change in subsidies is always larger than the variable cost savings they obtain because of having to meet less strict management requirements ($b_2^c$ versus $b_1^c$).

Next, we address the question how likely it is that $b_2^c \leq \hat{b} \leq b_1^c$. Or, equivalently, how likely is it that condition (6) holds in practice? As seen
before, a necessary condition is that the farmer type with low marginal conservation costs has larger fixed costs, i.e., \( F_1 > F_2 \). For a certain level of aggregate conservation, \( \bar{B} \), the difference \( F_1 - F_2 > 0 \) must lie between two bounds, as shown in (6).

Consider Figure 4, where we depict the complete information solution \((b'_1, b'_2)\), such that \( c'_1 = c'_2 = \mu \) and \( \bar{B} = \sum_i n_i b'_i \). Note that the left-hand side of (6) equals area \( 0AB \), while its right-hand side equals \( 0CD \). If \( F_1 - F_2 \) is larger than \( 0AB \) but smaller than \( 0CD \), the complete information solution is incentive compatible. Now assume an increase in the required
level of conservation effort, $\overline{B}$, increasing the corresponding individual effort levels to $(b_1', b_2')$. Graphically, it is easy to see that both the left- and right-hand side bounds of (6) increase, but that the increase of the right-hand side bound is larger (as $dbc_1/dbc_2 > 1$).\footnote{Mathematically, the bandwidth for $F_1 - F_2$ is given by $Z \equiv [c_2 (b_1) - c_1 (b_1)] - [c_2 (b_2) - c_1 (b_2)]$. If $\overline{B}$ increases by $d\overline{B}$, then $db_2 = d\overline{B}/[n_1(c_2'/c_1') + n_2] > 0$, and $db_1 = (c_2'/c_1')db_2 > db_2 > 0$. Hence, $dZ/d\overline{B} = \frac{d\overline{B}}{[n_1(c_2'/c_1') + n_2]}[c_2' (b_1) - c_1' (b_1)] > 0$.}

This analysis shows that, on the one hand, the interval for the ‘allowable’ difference in fixed costs (i.e., the range of differences in fixed costs that result in the complete information’s optimal policy being incentive compatible) increases if aggregate conservation effort $\overline{B}$ increases. On the other hand, a higher $\overline{B}$ also implies that the lower bound of the interval is increased, so that smaller differences in fixed costs prevent the complete information solution from being incentive compatible. As a consequence, when $F_1 > F_2$, only intermediate levels of aggregate conservation can be implemented without any informational distortions. Obviously, this range of intermediate aggregate conservation levels is directly related to the difference in farmers’ marginal costs. Therefore, the larger this difference, the larger the range of aggregate conservation levels with which the complete information’s optimal policy is incentive compatible.

6 Conclusions

This paper revisits the conclusions of the literature on incentive-compatible contracts and finds that, when taking into account the presence of fixed conservation costs, the double cost of separation (that is, the informational rents plus the distortions on individual conservation efforts) do not necessarily occur. While in the case of just variable costs the low-cost farmers always obtain an informational rent whereas the high-cost
farmers are confronted with less strict management requirements than under complete information, this is not necessarily the case when conservation entails fixed costs too. Then, if farmers with lower variable conservation costs face higher fixed costs (and vice versa), the complete information solution can be incentive compatible. Given the relevance of fixed costs in conservation issues, we conclude that incentive—compatible contracts should be given a second chance as a policy measure to induce conservation.

7 Appendix 1

The Lagrangian of the donor’s minimization problem in the presence of asymmetric information (see 5)) is the following

\[
L = n_1 S_1 + n_2 S_2 + \mu \left[ \overline{B} - n_1 b_1 - n_2 b_2 \right] + \sum \lambda_i \left[ F_i + c_i (b_i) - S_i \right] + \\
\gamma_1 [c_1 (b_1) - S_1 - c_1 (b_2) + S_2] + \gamma_2 [c_2 (b_2) - S_2 - c_2 (b_1) + S_1],
\]

where \( \mu \geq 0 \), \( \lambda_i \geq 0 \), \( \gamma_i \geq 0 \) are the corresponding Kuhn—Tucker multipliers.

The corresponding conditions for an optimum are:

\[
\lambda_1 c'_1 (b_1) - \mu n_1 + \gamma_1 c'_1 (b_1) - \gamma_2 c'_2 (b_1) = 0, \quad (10)
\]
\[
\lambda_2 c'_2 (b_2) - \mu n_2 - \gamma_1 c'_1 (b_2) + \gamma_2 c'_2 (b_2) = 0, \quad (11)
\]
\[
n_1 - \lambda_1 - \gamma_1 + \gamma_2 = 0, \quad (12)
\]
\[
n_2 - \lambda_2 + \gamma_1 - \gamma_2 = 0, \quad (13)
\]
\[
\mu \left[ \overline{B} - n_1 b_1 - n_2 b_2 \right] = 0; \quad \overline{B} - n_1 b_1 - n_2 b_2 \leq 0, \quad (14)
\]
\[
\lambda_i [F_i + c_i (b_i) - S_i] = 0; \quad F_i + c_i (b_i) - S_i \leq 0, \quad i = 1, 2, \quad (15)
\]
\[
\gamma_1 [c_1 (b_1) - S_1 - c_1 (b_2) + S_2] = 0; \quad c_1 (b_1) - S_1 - c_1 (b_2) + S_2 \leq 0, \quad (16)
\]
\[
\gamma_2 [c_2 (b_2) - S_2 - c_2 (b_1) + S_1] = 0; \quad c_2 (b_2) - S_2 - c_2 (b_1) + S_1 \leq 0, \quad (17)
\]

The case where \( \lambda_1 \geq 0 \), \( \lambda_2 \geq 0 \), \( \gamma_1 = \gamma_2 = 0 \) corresponds to
the complete information solution, where \( \mu = c'_1(b_1^c) = c'_2(b_2^c) > 0 \),
\( \mathcal{B} = n_1b_1^c + n_2b_2^c \) and \( F_i + c_i(b_i^c) - S_i^c = 0 \) for all \( i \), and has been discussed already in section 3. The complete information’s optimal policy is incentive compatible if and only if (16) and (17) hold, that is, when \( c_1(b_1^c) - S_1^c - c_1(b_2^c) + S_2^c \leq 0 \) and \( c_2(b_2^c) - S_2^c - c_2(b_1^c) + S_1^c \leq 0 \). Since \( S_i^c = F_i + c_i(b_i^c) \) for all \( i \), the two conditions reduce, respectively, to \( F_1 - F_2 \geq c_2(b_2^c) - c_1(b_2^c) \) and \( F_1 - F_2 \leq c_2(b_1^c) - c_1(b_1^c) \). Since \( c'_1(b_1^c) = c'_2(b_2^c) \) and \( c'_2(b) > c'_1(b) \) for all \( b > 0 \), we then have \( b_1^c > b_2^c \). Integrating over the relevant range, we can conclude that \( c_2(b_1^c) - c_1(b_1^c) > c_2(b_2^c) - c_1(b_2^c) \). Therefore, there exists a range of values for \( F_1 - F_2 \) such that the complete information’s optimal policy is incentive compatible, which is the following:

\[
  c_2(b_2^c) - c_1(b_2^c) \leq F_1 - F_2 \leq c_2(b_1^c) - c_1(b_1^c). 
\] (18)

Now assume that \( F_1 - F_2 < c_2(b_2^c) - c_1(b_2^c) \). Then, condition \( c_1(b_1^c) - S_1^c - c_1(b_2^c) + S_2^c \leq 0 \) does not hold. In the complete information solution, type 1 prefers the policy targeted at type 2. By (16), the incentive compatibility constraint for type 1 must be binding and \( \gamma_1 > 0 \). Note that \( \lambda_1 = \lambda_2 = 0 \) is not possible since (12) and (13) then yield \( n_1 = -n_2 \). Therefore, we can have either (i) \( \lambda_1 > 0, \lambda_2 = 0 \) or (ii) \( \lambda_1 = 0, \lambda_2 > 0 \).

Consider case (i) where \( \lambda_1 > 0 \) and \( \lambda_2 = 0 \). There are two subcases, (ia) \( \gamma_1 > 0 \) and \( \gamma_2 > 0 \) and (ib) \( \gamma_1 > 0 \) and \( \gamma_2 = 0 \). Clearly, subcase (ib) is not possible because, by (13), \( n_2 = -\gamma_1 < 0 \), which is a contradiction. Subcase (ia) corresponds to the uniform policy described in (3), where both incentive compatibility constraints are binding. In that case, conditions (10) and (11) reduce to:

\[
  \lambda_1 c'_1(b^u) - \mu n_1 + \gamma_1 c'_1(b^u) - \gamma_2 c'_2(b^u) = 0, 
\] (19)

\[
  -\mu n_2 - \gamma_1 c'_1(b^u) + \gamma_2 c'_2(b^u) = 0.
\] (20)
Combining both conditions we obtain \( \mu = c'_1(b^n) \). From (12) and (13), we have \( \lambda_2 = n_1 + n_2 \) and \( \gamma_1 = \gamma_2 - n_2 \). Substituting these expressions in (19), we then obtain \( \gamma_2 [c'_2(b^n) - c'_1(b^n)] = 0 \), which is only possible when \( \gamma_2 = 0 \), since we assume that \( c'_2(b) > c'_1(b) \) for all \( b > 0 \). But we were assuming \( \gamma_2 > 0 \), and therefore we obtain a contradiction. Thus, subcase (ia) is impossible either.

Now consider case (ii) where \( \lambda_1 = 0, \lambda_2 > 0 \). Again, two subcases are possible: (iia) \( \gamma_1 > 0, \gamma_2 > 0 \) and (iib) \( \gamma_1 > 0, \gamma_2 = 0 \). Subcase (iia) corresponds again to the possibility of a uniform policy. A similar procedure to the one described for subcase (ia) lead us to conclude that \( \gamma_1 = 0 \), which is a contradiction. Finally, we explore case (iib) \( \gamma_1 > 0, \gamma_2 = 0 \). The combination of equations (10) to (13) lead us to the optimality condition:

\[
n_1 [c'_2(b_2^*) - c'_1(b_2^*)] = n_2 [c'_1(b_1^*) - c'_2(b_2^*)],
\]

which characterizes the optimal separating policy, together with the conditions \( \overline{B} = n_1 b_1^* + n_2 b_2^*, S_1^* = F_2 + c_2(b_2^*) \) and \( c_1(b_1^*) - S_1^* = c_1(b_2^*) + S_2^* = 0 \).

Now, consider the case where \( F_1 - F_2 > c_2(b_2^*) - c_1(b_1^*) \). Then, condition \( c_2(b_2^*) - S_2^* - c_2(b_1^*) + S_1^* \leq 0 \) does not hold and, by (17), the incentive compatibility constraint for type 2 must be binding and \( \gamma_2 > 0 \). Now, in the complete information solution, type 2 prefers the policy targeted at type 1. A similar proof as the one described before lead us to conclude that the optimum in this case is characterized by \( \gamma_1 = 0, \lambda_1 > 0 \) and \( \lambda_2 = 0 \). Thus, combining equations (10) to (13), we now obtain the following optimality condition:

\[
n_2 [c'_2(b_1^*) - c'_1(b_1^*)] = n_1 [c'_1(b_1^*) - c'_2(b_2^*)],
\]

together with the conditions \( \overline{B} = n_1 b_1^* + n_2 b_2^*, S_1^* = F_1 + c_1(b_1^*) \) and \( c_2(b_2^*) - S_2^* - c_2(b_1^*) + S_1^* = 0 \). So, again, the optimal policy is a
separating one.

Summarizing, the optimal policy under incomplete information is always separating. If $F_1 - F_2$ is sufficiently small, there is a distortion: the complete information policy is not incentive compatible, and an informational rent is needed for type 1 farmers. Conversely, if $F_1 - F_2$ is sufficiently large, an informational rent is needed for type 2 farmers. Only for intermediate values of $F_1 - F_2$, the complete information solution can be implemented.
